

## Conversion of Binary to BCD to ASCII

- A binary number can be converted to BCD format by using repeated division by 10.
- The largest 16-bit binary number is 65,535 which has five decimal digits.
- The first division by 10 generates the least significant digit (in the remainder).
- The ASCII code of a digit can be obtained by adding \$30 to it.
- The ASCII code of 0 is "\$30", the Ascii code of 1 is 31 and so on

	Quotient	Remainder	
$\begin{array}{r} 12345 \\ \hline 10 \end{array}$	1234	5	Least significant
$\begin{array}{r} 1234 \\ \hline 10 \end{array}$	123	4	
$\begin{array}{r} 123 \\ \hline 10 \end{array}$	12	3	
$\begin{array}{r} 12 \\ \hline 10 \end{array}$	1	2	
$\begin{array}{r} 1 \\ \hline 10 \end{array}$	0	1	Most significant

**Example:** Write a program to convert the 16-bit number stored at \$1000-\$1001 to BCD format and store the result at \$1010-\$1014. Convert each BCD digit into its ASCII code and store it in one byte.

```
        org $1000
data    dc.w 12345        ;data to be tested
        org $1010
result  ds.b 5           ; reserve bytes to store the result
        org $1500
        ldd data          ;D = the number to be converted
        ldy #result       ;Y = the first address of result
        ldx #10           ;X =10
        idiv              ;D/X → X, R→D
        addb #$30         ;convert the digit into ASCII code
        stab 4,Y          ;save the least significant digit

        xgdx
        ldx #10
        idiv
        addb #$30
```

```

stab 3,Y ; save the second to least significant digit

xgdx
ldx #10
idiv
addb #$30
stab 2,Y ; save the middle digit

xgdx
ldx #10
idiv
addb #$30
stab 1,Y ; save the second most significant digit

xgdx
addb #$30
stab 0,Y ; save the most significant digit

```

- If the number is less than 5 digits, we get zeros at left and do unnecessary operations for example: 345 will be 5, 4, 3, 0, 0, 0
- Two improvements: (1) loop can be used to reduce the program and (2) a condition to exit the loop when the quotient = 0
